
PRIOR STUDY
Jev-Routed Temporal Granularity
PART 1 · JevGAG report
precondition audit, T4 + A100
PART 2 · DDAG method
regime-aware granularity
cost
granularity cost is a hardware property
signal
cheap context statistics do not predict coarse-unsafe segments
endpoint
the internal reference flips between GPUs
P1 · break-even law
per-forward ratio vs. NFE break-even, both GPUs
P2 · signal
hand-crafted 0.491 (fails) · Jev text 0.788
P3 · endpoint
an endpoint independent of the compared modes
regime map
the paying regime per (mode, GPU)
intrinsic probe
prefill activations 0.798; with residual 0.842
independent endpoints
pixel · flicker · Jev · seam repair (−25%)
Jev thread. JevGAG grounds the audit on a System One oracle: Jev text is the only pre-generation signal that works in the report (0.788); Jev image certifies identity independently (ρ = +1.000 vs. CLIP); a typed Jev critic on raw frames is bounded — decision models need context, not pixels alone.
Outcome. a regime map plus calibrated components. Across T4 and A100, and across latent, pixel and flicker endpoints, the cheap mode was never worse: the optimal policy is a fixed mode, and the map states exactly where adaptivity becomes worth deploying.
